

GEANT4 BEGINNERS COURSE

GSSI, L'Aquila (Italy)
6-10 July 2015

Physics in Geant4: Particles, processes, cuts and models

Geant 4 tutorial course

Introduction

Mandatory user classes in a Geant4:

- **G4VUserPrimaryGeneratorAction**
- **G4VUserDetectorConstruction**
- **G4VUserPhysicsList**

*Particles, physics processes, and cut-off parameters to be used in the simulation must be defined in the **G4VUserPhysicsList** class*

Why a physics list?

- “*Physics is physics* – shouldn't Geant4 provide, as a default, a complete set of physics that everyone can use?”
- **NO:**
 - Software can only capture Physics through a modelling
 - No unique Physics modelling
 - Very much the case for hadronic physics
 - But also the electromagnetic physics
 - Existing models still evolve and new models are created
 - Some models are more suited to some energy ranges
 - Medical applications not interested in multi-GeV physics in general
 - HEP experiments not interested in effects due to atomic shell structure
 - computation speed is an issue
 - a user may want a less-detailed, but faster approximation

Why a physics list?

- For this reason Geant4 takes an atomistic, rather than an integral approach to physics
 - provide many physics independent components (processes)
 - user selects these components in custom physics lists
- This physics environment is built by the user in a flexible way:
 - picking up the particles he/she wants
 - picking up the physics to assign to each particle
- User must have a good understanding of the physics required
 - omission of particles or physics could cause errors or poor simulation

User may also use some provided “ready-to-use” physics list

G4VUserPhysicsList: required methods

ConstructParticle () :

- choose the particles you need in your simulation, define all of them here

ConstructProcess () :

- for each particle, assign all the physics processes relevant to your simulation
 - What's a process ?
 - a class that defines how a particle should interact with matter, or decays
 - » it's where the physics is!

SetCuts () :

- Set range cuts for secondary particle production
 - What's a range cut ?
 - a threshold on particle production
 - » Secondary Particles unable to travel at least the range cut value are not produced

Particles: basic concepts

There are three classes to describe a particle in Geant4:

- **G4ParticleDefinition**
 - defines a particleaggregates information to characterize a particle's properties (name, mass, spin, etc...)
- **G4VDynamicParticle**
 - describes a particle interacting with materialsaggregates information to describe the dynamic of particles (energy, momentum, polarization, etc...)
- **G4VTrack**
 - describes a particle travelling in space and timeincludes all the information for tracking in a detector simulation (position, step, current volume, track ID, parent ID, etc...)

Definition of a particle

Geant4 provides the **G4ParticleDefinition** definition class to represent a large number of elementary particles and nuclei, organized in six major categories:

lepton, meson, baryon, boson, shortlived and ion

- Each particle is represented by its own class, for example **G4Electron**, which is derived from `G4ParticleDefinition`
- Properties characterizing individual particles are “read only” and can not be changed directly

User must define all particles type which are used in the application: not only primary particles but also all other particles which may appear as secondaries generated by the used physics processes

Constructing particles

Due to the large number of particles can be necessary to define, this method sometimes can be not so comfortable

```
void
MyPhysicsList::ConstructParticle()
{
    G4Electron::ElectronDefinition();
    G4Proton::ProtonDefinition();
    G4Neutron::NeutronDefinition();
    G4Gamma::GammaDefinition();
    ....
}
```

It is possible to define **all** the particles belonging to a **Geant4 category**:

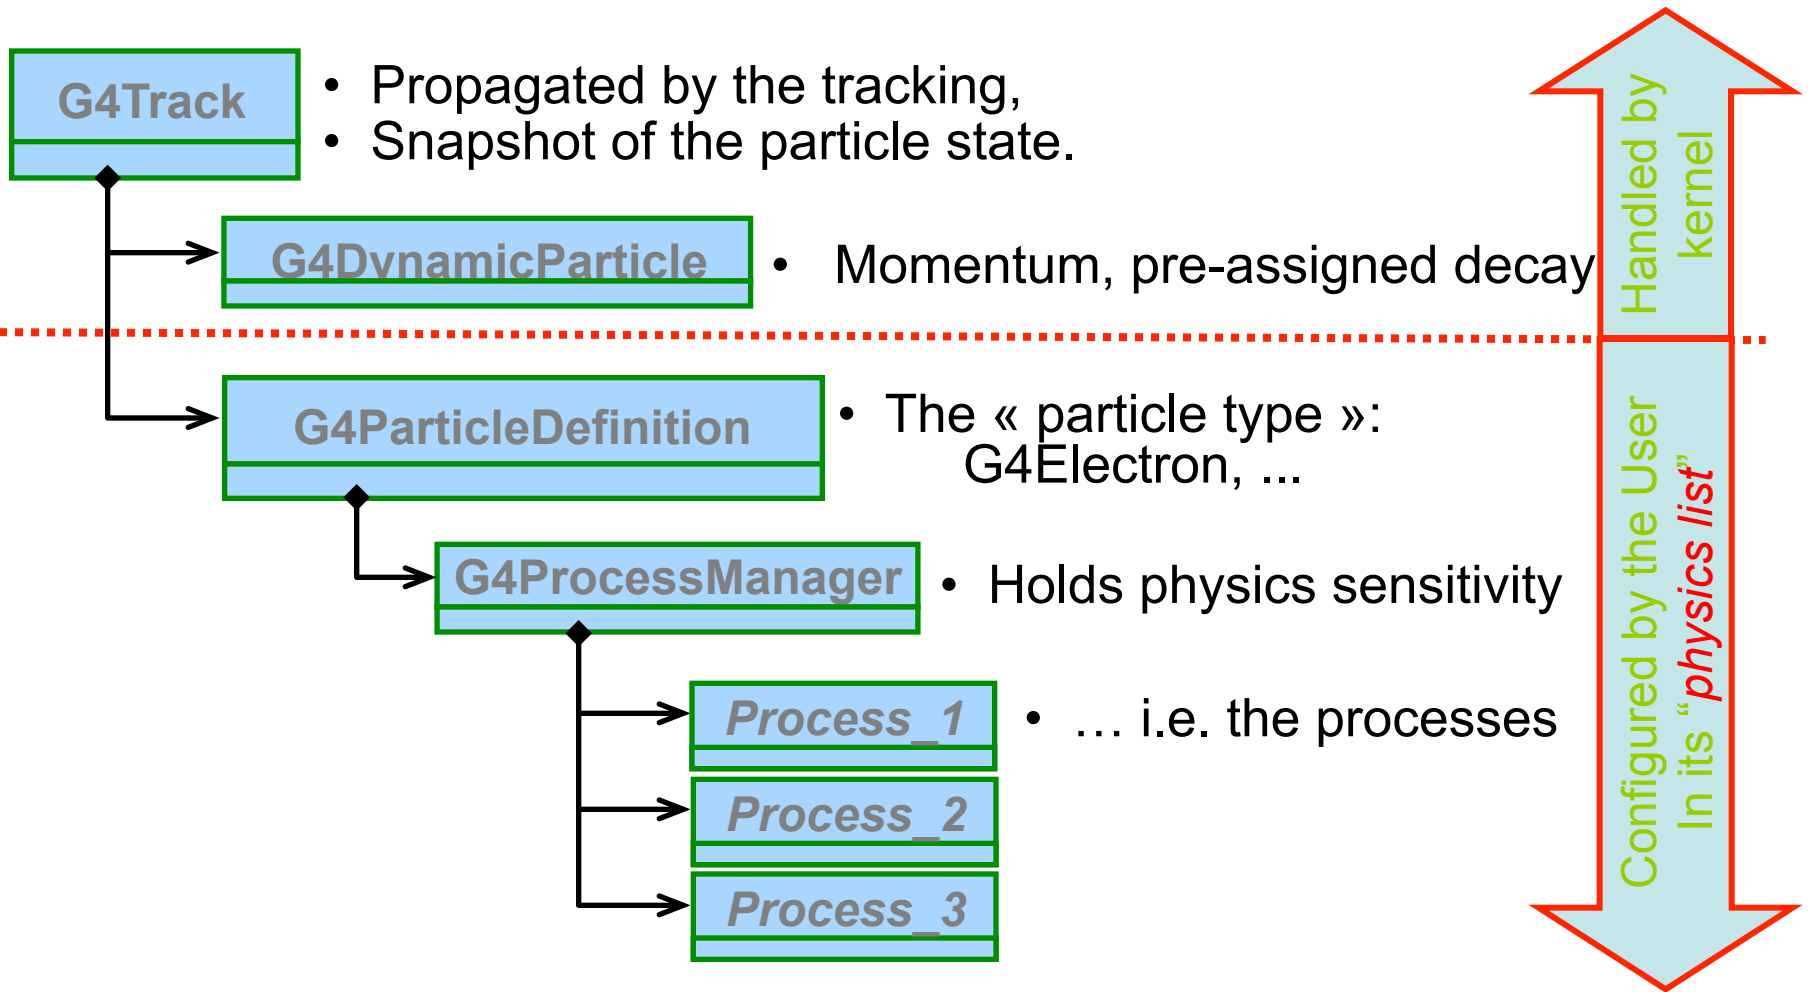

- **G4LeptonConstructor**
- **G4MesonConstructor**
- **G4BaryonConstructor**
- **G4BosonConstructor**
- **G4ShortlivedConstructor**
- **G4IonConstructor**

```
void
MyPhysicsList::ConstructBaryons()
{
    // Construct all baryons
    G4BaryonConstructor pConstructor;
    pConstructor.ConstructParticle();
}
```

From particles to processes

Processes

Physics processes describe how particles interact with materials

Geant4 provides seven major categories of processes:

- Electromagnetic
- Hadronic
- Decay
- Optical
- Photolepton_hadron
- Parameterization
- Transportation

A process does two things:

- 1) decides when and where an interaction will occur
 - methodS: **GetPhysicalInteractionLength** → *limit the step*
 - this requires a cross section
 - for the transportation process, the distance to the nearest object
- 2) generates the final state of the interaction (changes momentum, generates secondaries, etc.)
 - methodS: **DoIt**
 - this requires a model of the physics

G4VProcess class

Physics processes are derived from the **G4VProcess** base class

- Abstract class defining the common interface of **all processes** in Geant4:
 - Used by all physics processes (also by the transportation, etc...)
 - Defined in **source/processes/management**

- Define **three kinds of actions**:

- **AtRest** actions:

- Decay, e^+ annihilation ...

- **AlongStep** actions:

- To describe (inter)actions, continuously occurring along the particle path, like ionisation;

- **PostStep** actions:

- To describe point-like (inter)actions, like decay in flight, hadronic interactions ...

A process can implement a combination of them (decay = AtRest + PostStep)

Example processes

- Discrete process: **Compton Scattering, hadronic inelastic, ...**
 - step determined by cross section, interaction at end of step
 - PostStepGPIL(), PostStepDolt()
- Continuous process: **Cerenkov effect**
 - photons created along step, roughly proportional to step length
 - AlongStepGPIL(), AlongStepDolt()
- At rest process: **mu- capture at rest**
 - interaction at rest
 - AtRestGPIL(), AtRestDolt()
- Rest + discrete: **e+ annihilation, decay, ...**
 - both in flight and at rest
- Continuous + discrete: **ionization**
 - energy loss is continuous
 - knock-on electrons (δ -ray) are discrete

pure

combined

Handling multiple processes

- STAGE 1: a particle is shot and “transported”
- STAGE 2: all processes associated to the particle propose a geometrical step length (depends on process cross-section)
- STAGE 3: The process proposing the shortest step “wins” and the particle is moved to destination
- STAGE 4: All processes “along the step” are executed and E_{kin} updated
- STAGE 5: “post step” phase of the process that limited the step is executed
New tracks are “pushed” to the stack
- STAGE 6: If $E_{\text{kin}}=0$ all “at rest” processes are executed; if particle is stable the track is killed. Else:
- STAGE 7: A new step starts and sequence repeats...

Processes return a “true path length”. The multiple scattering “virtually folds up” this true path length into a shorter “geometrical” path length. Transportation process can limit the step to geometrical boundaries.

Production thresholds: cut

Each simulation developer must answer the question:
how low can I go?

- should I produce (and track) every secondary or should I consider thresholds?

This is a balancing act:

Production thresholds: cut

- The **traditional Monte Carlo** solution is to impose an absolute **cutoff in energy** (tracking cut):
 - particles are stopped when this energy is reached
 - remaining energy is dumped at that point
- But, such a cut may cause **imprecise stopping location** and localization of energy deposition
- There is also a **particle dependence**
 - range of 10 keV p in Si is different from range of 10 keV e⁻ in Si
- And a **material dependence**
 - suppose you have a detector made of alternating sheets of Pb and plastic scintillator
 - if the cutoff is OK for Pb, it will likely be wrong for the scintillator which does the actual energy deposition measurement

Production thresholds: cut

- In Geant4 there are no tracking cuts
 - particles are tracked down to a zero range/kinetic energy
- Only production cuts exist
 - i.e. cuts allowing a particle to be born or not
 - Applied to: **gamma**, **electron**, **positron**, **proton**
- *Why are production cuts needed ?*

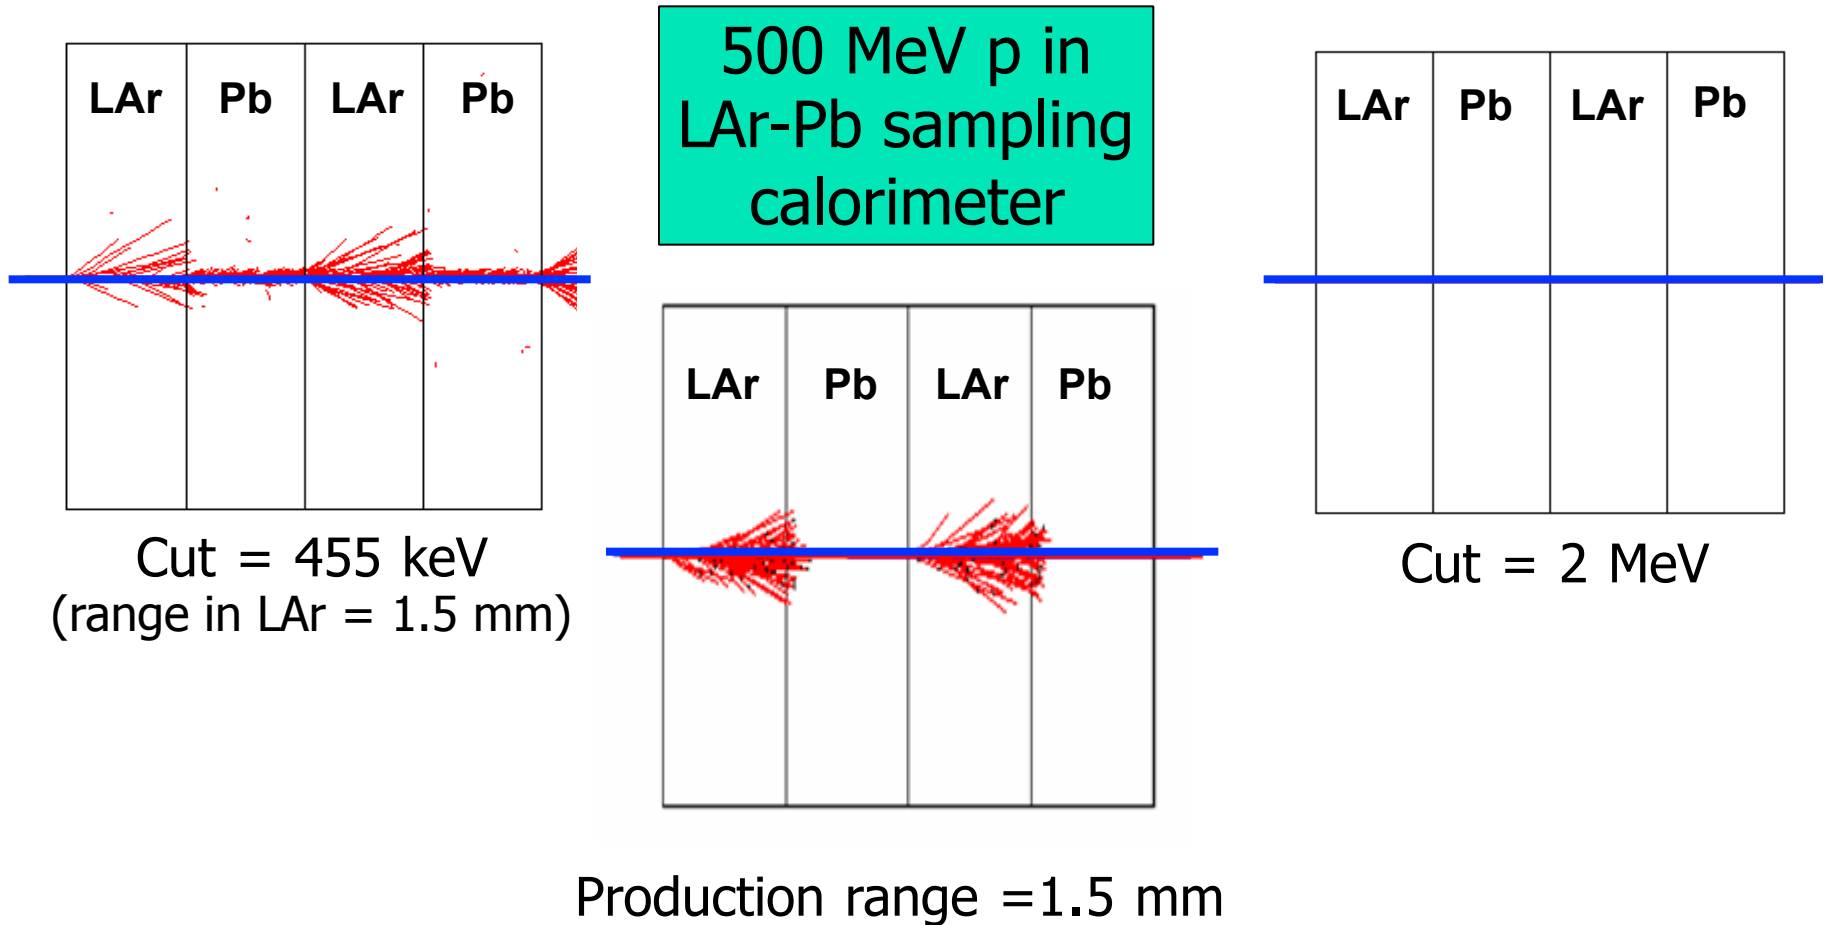

Some electromagnetic processes involve infrared divergences

- this leads to a huge number of soft photons/electrons (such as in Bremsstrahlung, δ -ray production)
- production cuts limit this production to particles above the threshold
- the remaining, divergent part is treated as a continuous effect (i.e. AlongStep action) \rightarrow Energy balance is preserved

Production thresholds: cut

- Geant4 solution: impose a “range” production threshold
 - Range cutoff instead of energy cutoff
 - default = 1 mm
- Only one production threshold cut is uniformly set
- Production threshold is internally converted to an energy threshold, depending on particle type and material
- When primary no longer has enough energy to produce secondaries which travel at least 1mm, two things happen:
 - discrete energy loss stops (no more secondaries produced)
 - the primary is tracked down to zero energy using continuous energy loss
 - Stopping location is therefore correct

Production thresholds: cut

Threshold in range: 1.5 mm

455 keV electron energy in liquid Ar
2 MeV electron energy in Pb

Cuts per region

- A complex detector may be composed by many different sub-detectors:
 - finely segmented volumes
 - very sensitive materials
 - large, undivided volumes
 - inert materials
- The same cuts may not be appropriate for all of these
 - User can define regions (logical volume envelopes) and assign different cuts for each region
- **Warning: this feature is for users who are**
 - **simulating complex detectors**
 - **experienced at simulating EM showers in matter**
 - **Good practice: cross check with uniform set of cuts to avoid biases**

Thanks for your attention
